

GitLab Product Documentation – RAG Test Document

1. GitLab Project

A GitLab project is a workspace used to manage source code, issues, merge requests, CI/CD pipelines, and other development activities. A project can be created as public, internal, or private depending on the required visibility.

2. GitLab Repository

A GitLab repository stores the files and revision history of a project. Developers use the repository to commit, branch, merge, and manage source code.

3. GitLab CI/CD

GitLab CI/CD automates software development workflows such as building, testing, and deploying applications. CI/CD configuration is commonly defined in a file named `.gitlab-ci.yml` in the repository.

4. GitLab Runner

A GitLab Runner is an application that executes CI/CD jobs. A pipeline can assign jobs to available runners based on tags and configuration.

5. Merge Request

A merge request is used to propose changes from one branch to another. It allows team members to review changes, discuss them, run checks, and merge approved changes.

6. GitLab Issue

A GitLab issue is used to track work such as bugs, feature requests, tasks, and discussions. Issues can be assigned to users and organized with labels.

7. Personal Access Token

A personal access token can be used to authenticate certain GitLab API requests and other Git operations. Tokens should be stored securely and must not be exposed in source code.

8. GitLab Visibility

GitLab projects can use visibility levels such as Public, Internal, or Private. The selected visibility controls who can access the project.

Purpose of this document

This small document is intentionally designed for RAG testing. Questions should be answered only from the information contained in this document. If a question asks for information that is not present here, the assistant should say that the information is not available in the provided documentation.
